

Using Machine Learning and Optical Character Recognition

to adaptively process text in pictures and scans

I. INTRODUCTION

Machine Learning has seen a massive demand in computer applications over the past few years. From self-driving cars to voice assistants like Siri, Machine Learning makes it possible for the computer to solve such hard problems. Our research aims to apply Machine Learning in image processing and OCR. OCR stands for Optical Character Recognition. It is used to read text from images such as a scanned document or a picture. This technology is used to convert, virtually any kind of images containing written text (typed, handwritten, or printed) into machine-readable text data.

OCR has two major building blocks:

- Text Detection
- Text Recognition

Text detection or in general object detection has been an area of intensive research accelerated with deep learning. Today, object detection, and in our case, text detection, can be achieved through two approaches:

- Region-based Detection
- Single Shot Detection

Region-based methods work by doing multiple passes to process the input. They first try to find all the regions which have objects the application can recognize, then, pass the regions detected to a classifier engine, which as its name suggests, it classifies the regions into the types we specify.

A single shot method on the other hand, tries to find the regions and the type at the same time, or in a single shot. Since this is a single step process, it is usually much faster but the downside of this being that it struggles with bad quality inputs and smaller objects.

II. OBJECTIVES

The main objective of this research is developing an intelligent and adaptable character recognition is able to extract text and numbers from any type of card provided, these being credit or gift cards with high level of accuracy,

regardless if the input is a scan or a photo. We will be experimenting with both methods mentioned, Region-based detection and Single shot detection, and see which provides a better performance given our constraints and input quality. We will gather enough data and samples to create our own dataset and train our model to our specific cards to get a better accuracy than what broadly used datasets and pre-trained models provide.

Optical Character Recognition will accurately translate into plain text. Since gift card design varies, image processing needs to be dynamic. Our next goal is to use machine learning to classify different pin cover designs. To create a Neural Network, we will need to collect pin covers from our gift card database and create a dataset. Our goal for this classifier is to accurately distinguish different pin covers. Our final goal is to use our program to use both Optical Character Recognition and Machine Learning to parse gift card information.

III. METHODS

The research uses gift card entry from a database that contains gift card image filename, SKU number, and card id. For each entry in the database, we are checking if the image exists. The gift card images are stored in UNLV's gpu server, @gpu.cs.unlv.edu. To parse gift card information from an image, we are using Python and libraries such as OpenCV and PyTesseract. For the initial part of the parsing, we are using image processing techniques to turn the image into black and white. Turning the image into a black and white image is necessary because our OCR library only accepts black and white image. The research has also seen great improvement in accuracy using other image processing techniques such as denoise. Our next step is to use our OCR library to turn the black and white image into text. After we get the text, we confirm if the image contains the SKU and card id that was stored in the database. By following these methods, we are able to check the accuracy of different OCR libraries and different image processing techniques.

IV. ACKNOWLEDGEMENT

We would like to thank UNLV's Center for Academic Enrichment and Outreach and the Office of Undergraduate Research for funding this research.
